

## December Tip of the Month

### Airflow and Placement

The placement of your commercial refrigeration equipment is critical to efficient operation. Placing a refrigerator or display case near a hot stove or oven will make it more difficult for your equipment to keep its contents cool, decreasing energy efficiency, and putting more wear and tear on the condenser.

Proper airflow inside and outside your equipment is essential to maintain efficient operation and minimize breakdowns. Make sure that no items are blocking the fans or air vents inside refrigerators and there is a cushion of space outside the unit. This way the condenser can effectively cycle out heat from inside the unit to maximize shelf life and keep your products fresh.
